ATTORNEY'S DOCKET NO. PH5-075

1 **TECHNICAL FIELD**

2 The present invention provides communication devices, communication
3 systems, a Bluetooth communication protocol communication device, and
4 communication methods.

5
6 **BACKGROUND OF THE INVENTION**

7 Conventional cordless telephone configurations include a handset coupled
8 via radio connection with a base station. The base station is usually
9 connected by wire to a traditional Public Switched Telephone Network (PSTN)
10 or an Integrated Services Digital Network (ISDN). The development of new
11 cordless standards which are based upon digital technology provides a broad
12 spectrum of applications. Exemplary cordless applications include wireless
13 Private Automatic Branch Exchange (PABX), wireless Local Area Network
14 (LAN), Telepoint, and Radio Local Loop. Cordless standards include for
15 example Digital Enhanced Cordless Telecommunications (DECT), Bluetooth,
16 GSM, PHS, AMPS, IS54 or IS95. The digital cordless telephones represent
17 a valid alternative to cellular phones in densely populated areas.

18 DECT is a cordless standard defined as a Multicarrier (MC), Time
19 Division Multiple Access (TDMA)/Time Duplex Division (TDD) system. Time
20 is divided in the DECT standard into frames of 10 ms. Each frame is
21 divided into 24 full slots. The standard also allows for half slots and double
22 slots of data.

23 In order to be able to support multiple channels, a DECT base station
24 compresses and transmits 10 ms of speech during one full slot. This means

15
16 **DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS**

17 This disclosure of the invention is submitted in furtherance of the
18 constitutional purposes of the U.S. Patent Laws "to promote the progress of
19 science and useful arts" (Article 1, Section 8).

20 According to a first aspect, a communication device comprises: a single
21 buffer configured to store communication data; control circuitry coupled with
22 the buffer and configured to generate a plurality of packets including different
23 amounts of communication data from the buffer; and communication circuitry
24 coupled with the control circuitry and configured to communicate the packets.

1 buffer and configured to generate a plurality of packets including different
2 amounts of communication data from the buffer; and communication circuitry
3 coupled with the control circuitry and configured to communicate the packets.

4 Another aspect provides a Bluetooth communications protocol
5 communication device comprising: a cyclical buffer configured to store a
6 maximum amount of communication data to be communicated in a single
7 packet, the communication data comprising a plurality of data samples; a
8 packet composer coupled with the buffer and configured to switch between
9 generation of packets of a first packet type individually including a first
10 amount of communication data from the buffer and of packets of a second
11 packet type individually including a second amount of communication data
12 from the buffer, the packet composer being further configured to extract
13 communication data from only a portion of the buffer for packets of the first
14 packet type selectively using an offset address and the entire buffer for
15 packets of the second packet type, and wherein the packet composer is further
16 configured to extract communication data only from a first portion of the
17 buffer for a first packet of the first packet type and only from a second
18 portion of the buffer for a second packet of the first packet type and only
19 from a third portion of the buffer for a third packet of the first packet type;
20 and wireless communication circuitry coupled with the packet composer and
21 configured to communicate the packets of the first packet type and the second
22 packet type in accordance with a Bluetooth communications protocol.

23 Another aspect provides a communication method comprising: storing
24 communication data within a single buffer; extracting different amounts of

As shown, plural data paths 54, 56 are provided within communication device 22 intermediate data circuitry 30, and communication circuitry 32. Data path 54 may be referred to as a transmit path and data path 56 may be referred to as a receive data path. Data path 54 communicates data from data circuitry 30 to communication circuitry 32 while data path 56 communicates data from communication circuitry 32 to data circuitry 30.

Port interface 40 operates to communicate data intermediate data circuitry 30 and port DMA 42. Port DMA 42 and TDMA DMA 48 operate to address buffers 44, 46 to access (or extract) data and store data from a port side and a communication side, respectively, of buffers 44, 46.

In the described embodiment, buffers 44, 46 are individually implemented as a single cyclical buffer having a length to hold data for a packet with a longest interval time (e.g., to store the maximum amount of communication data to be communicated in a single packet using communication circuitry 32). Packets HV2 have the longest interval time in the described embodiment with lesser bit (FEC) protection. Other packets (e.g., HV1 packets) are communicated by devices 22 which include an amount of communication data different than the maximum amount stored by one of buffers 44, 46 as described below.

Data circuitry 30 operates to generate data to be communicated using communication circuitry 32 and/or to process data received from communication circuitry 32. In an exemplary embodiment, data circuitry 30 comprises data sampling circuitry which is configured in one exemplary arrangement to provide ADPCM samples of data to be communicated or to generate a

1 read by the port side during such given frame. In the depicted example,
2 receive frame references of receive buffer 46 are shifted in time relative to
3 transmit frame references of transmit buffer 44 and the TDMA frame reference
4 of graph 88).

5 As shown in Fig. 7, data is written from a packet to second portion
6 64 of receive buffer 46 (represented by HV1 WR2 in graph 84) while data
7 from second portion 62 is read by the port side (represented by RD2 in
8 graph 86). Such continues for both first portion 64 and second portion 66
9 of buffer 46 during the high quality communications as shown. During
10 receive communications, data is written from a packet (e.g., such as data
11 sample 0) just before it is read by the port side.

12 At a moment in time intermediate frame 0 and frame 1 of graph 88
13 corresponding to time portions 78 and 79, system controller 52 switches
14 communications from a high quality voice link (HV1 packet type) to a lesser-
15 quality voice link (HV2 packet type) with less bit protection than the high-
16 quality voice link. Other communications via another link are possible during
17 frame 2 and frame 4 during the second format communications period 79 as
18 shown.

19 During transmit operations of second format communications (HV2
20 packets), first portion 60 of transmit buffer 44 is written to by the port side
21 during a given frame (WR1) and first portion 60 and second portion 62 are
22 both read by the packet side for provision in a packet (represented by HV2
23 RD). During a subsequent frame, the second portion 62 of transmit buffer
24
